Spatial Data Science

Data Grammar

(EPA122A)

Lecture 3

Trivik Verma

Kung Fu Panda is property of DreamWorks and Paramount Pictures

Correlation supersedes causation, and science can advance even without coherent models, unified theories, or really any mechanistic explanation at all.

The End of Theory: The Data Deluge Makes the Scientific Method Obsolete

Illustration: Marian Bantjes "All models are wrong, but some are useful." So proclaimed statistician George Box 30 years ago, and he was right. But what choice did we have? Only models, from cosmological equations to theories of human behavior, seemed to be able to consistently, if imperfectly, explain the world around us. Until now. Today companies [...]

Ask a Question How were the data **sampled**? Get the data Which data are **relevant**? Are there **privacy** issues? Explore the data Model the data Communicate results

Data Science Process	Inclusion Who is (not) included in the data?	Inequality What role does inequality play in data science methods?	Participation Who is (not) involved in the data science process?	Power How does the data reflect existing power dynamics?	Positionality What is your own positionality with the research?
Collect & Combine Data Contexts and power relations that lie beneath data collection & creation of data sets	Who is at the center of this data collection process? Pay particular attention to data collection with/from neglected and historically excluded groups (Boyd, 2021a; Lee et al., 2022).	Are structural inequalities reflected in the data collection process? (Boyd, 2021a). For example, is the method suggesting the use of proxies or aggregated data? How does the sampling method influence this? The latter includes considerations of past developments that have caused these structural inequalities (Harrington et al., 2021). Are there alternative data sources that might improve visibility of certain groups?	Are all relevant stakeholders included in the data collection? Obtain data as close to the source as possible. Actively seek the help of those that are living the experience/topic of interest (Lee et al., 2022).	Acknowledge that the data does not belong to the collector, but is borrowed from the people that produce the data (Harrington et al., 2021; Nash et al., 2022). Have you obtained informed consent from those that produce the data by explaining the need, goal, and use of their data?	 Critically reflect on your data collection choices (Boyd, 2021a): 1. Why are you collecting data from these specific sources? Why are you using this specific sampling method? 2. Why are you including these specific stakeholders? 3. How are you silencing certain voices by excluding them in the data collection and your data set? And why? 4. How are you amplifying certain voices by including them in the data collection and your data set? And why?

Types of Data

Types of Data

What kind of values are in your data (data types)?

Simple or atomic:

Numeric: integers, floats **Boolean**: binary or true false values $\longrightarrow 0_{1}$ $T_{1}F$ **Strings**: sequence of symbols nbois La "abcde" "156-fgho/-]"

Data Types

What kind of values are in your data (data types)? Compound, composed of a bunch of atomic types:

Date and time: compound value with a specific structure

Lists: a list is a sequence of values

Dictionaries: A dictionary is a collection of key-value pairs, a pair of values *x* : *y* where *x* is usually a string called the key representing the "name" of the entry, and *y* is a value of any type.

Example: Student record: what are x and y? First: Trivik Last: Verma Classes: [EPA1316, EPA1352]

Data Storage

How is your data represented and stored (data format)?

- **Tabular Data:** a dataset that is a two-dimensional table, where each row typically represents a single data record, and each column represents one type of measurement (csv, dat, xlsx, etc.).
- Structured Data: each data record is presented in a form of a [possibly complex and multi-tiered] dictionary (json, xml, etc.)
- Semi structured Data: not all records are represented by the same set of keys or some data records are not represented using the key-value pair structure.
- **Geographic Data:** (shp, dbx, shx...)

Tabular Data

In tabular data, we expect each record or observation to represent a set of measurements of a single object or event.

hu	ibway_d ibway_d	ata = pd.r ata.head()	ead_cs	v('hubwa	y_trips.c	sv', low_	memory=Fa	alse)

This example and all material are provided by the <u>Data Science course</u> at Harvard University

Tabular Data

Each type of measurement is called a variable or an attribute of the data (e.g. seq_id, status and duration are variables or attributes).

- The number of attributes is called the dimension. These are often called features.
- We expect each table to contain a set of records or observations of the same kind of object or event (e.g. our table above contains observations of rides/checkouts).

First Look At The Data

In [27]: hubway_data = pd.read_csv('hubway_trips.csv', low_memory=False)
hubway_data.head()

Out[27]:		seq_id	hubway_id	status	duration	start_date	strt_statn	end_date	end_statn	bike_nr	subsc_type	zip_code	birth_da
	0	1	8	Closed	9	7/28/2011 10:12:00	23.0	7/28/2011 10:12:00	23.0	B00468	Registered	'97217	1976.0

	4	5	12	Closed	12	7/28/2011 10:37:00	23.0	7/28/2011 10:37:00	23.0	B00554	Registered	'97214	1983.0

Types of Data

Important to distinguish between classes of variables or attributes based on the type of values they can take on.

- **Quantitative variable:** is numerical and can be either:
 - **discrete** a finite number of values are possible in any bounded interval.
 - For example: "Number of siblings" is a discrete variable
 - **continuous** an infinite number of values are possible in any bounded interval.
 - For example: "Height" is a continuous variable
- Categorical variable: no inherent order among the values
 - For example: "What kind of pet you have" is a categorical variable

Common Issues

Common issues with data:

- Missing values: how do we fill in?
- Wrong values: how can we detect and correct?
- Messy format
- Not usable: the data cannot answer the question posed

Messy Data

- The following is a table accounting for the number of produce deliveries over a weekend.
- What are the variables in this dataset? What object or event are we measuring?

	Friday	Saturday	Sunday
Morning	15	158	10
Afternoon	2	90	20
Evening	55	12	45

What's the issue? How do we fix it?

Messy Data

We're measuring individual deliveries; the variables are Time, Day, Number of Produce.

	Friday	Saturday	Sunday
Morning	15	158	10
Afternoon	2	90	20
Evening	55	12	45

Problem: each column header represents a single value rather than a variable. Row headers are "hiding" the Day variable. The values of the variable, "Number of Produce", is not recorded in a single column.

Fixing Messy Data

We need to reorganize the information to make explicit the event we're observing, and the variables associated to this event.

ID	Time	Day	Number
1	Morning	Friday	15
2	Morning	Saturday	158
3	Morning	Sunday	10
4	Afternoon	Friday	2
5	Afternoon	Saturday	9
6	Afternoon	Sunday	20
7	Evening	Friday	55
8	Evening	Saturday	12
9	Evening	Sunday	45

Tabular = Happy Me 😳

Common causes of messiness are:

- Column headers are values, not variable names
- Variables are stored in both rows and columns
- Multiple variables are stored in one column/entry
- Multiple types of experimental units stored in same table

In general, we want each file to correspond to a dataset, each column to represent a single variable and each row to represent a single observation.

We want to **tabularize** the data. This makes Python happy.

Grammar

Exploratory Data Analysis (EDA)

Why?

- EDA encompasses the *"explore* data" part of the data science process
- EDA is crucial but often overlooked:
 - If your data is bad, your results will be bad
 - Conversely, understanding your data well can help you create smart, appropriate models

Exploratory Data Analysis (EDA)

What?

- Store data in data structure(s) that will be convenient for exploring/processing (Memory is fast. Storage is slow)
- 2. Clean/format the data so that:
 - Each row represents a single object/observation/entry
 - Each column represents an attribute/property/feature of that entry
 - Values are numeric whenever possible
 - Columns contain atomic properties that cannot be further decomposed*

* Unlike food waste, which can be composted. Please consider composting food scraps.

Exploratory Data Analysis (EDA)

What? (continued)

- 3. Explore *global* properties: use histograms, scatter plots, and aggregation functions to summarize the data
- 4. Explore *group* properties: group like-items together to compare subsets of the data (are the comparison results reasonable/expected?)

This process transforms your data into a format which is easier to work with, gives you a basic overview of the data's properties, and likely generates several questions for you to follow-up in subsequent analysis. **fu**Delft

EDA: without Pandas

Say we have a small dataset of the top 50 most-streamed Spotify songs, globally, for 2019.

EDA: without Pandas

Say we have a small dataset of the top 50 most-streamed Spotify songs, globally, for 2019.

NOTE: The following music data are used purely for illustrative, educational purposes. The data, including song titles, may include explicit language. TU Delft, including myself and the rest of the EPA1316 staff, does not endorse any of the entailed contents or the songs themselves, and we apologise if it is offensive to anyone in anyway.

EDA: without Pandas

top50.csv

Each row represents a distinct song. The columns are:

- **ID:** a unique ID (i.e., 1-50)
- TrackName: Name of the Track
- ArtistName: Name of the Artist
- **Genre:** the genre of the track
- **BeatsPerMinute:** The tempo of the song.
- **Energy:** The energy of a song the higher the value, the more energetic.
- **Danceability**: The higher the value, the easier it is to dance to this song.
- **Loudness**: The higher the value, the louder the song.
- **Liveness**: The higher the value, the more likely the song is a live recording.
- Valence: The higher the value, the more positive mood for the song.
- **Length**: The duration of the song (in seconds).
- **Acousticness**: The higher the value, the more acoustic the song is.
- **Speechiness**: The higher the value, the more spoken words the song contains.
- **Popularity**: The higher the value, the more popular the song is.

EDA: without Pandas

				BeatsPer				Live				Speechi	
	TrackName	ArtistName	Genre	Minute	Energy	Danceability	Loudness	ness	Valence	Length	Acousticness	ness	Popularity
1	Senorita	Shawn Menc	canadian pop	117	55	76	-6	8	75	191	4	3	79
2	China	Anuel AA	reggaeton flow	105	81	79	-4	8	61	302	8	9	92
3	boyfriend (w	Ariana Grand	dance pop	190	80	40	-4	16	70	186	12	46	85
4	Beautiful Peo	Ed Sheeran	рор	93	65	64	-8	8	55	198	12	19	86

Q1: What are some ways we can store this file into data structure(s) using regular Python (not the Pandas library).

EDA: without Pandas

						top50.csv	,						
				BeatsPer				Live				Speechi	
	TrackName	ArtistName	Genre	Minute	Energy	Danceability	Loudness	ness	Valence	Length	Acousticness	ness	Popularity
1	Senorita	Shawn Menc	canadian pop	117	55	76	-6	8	75	191	4	3	79
2	China	Anuel AA	reggaeton flow	105	81	79	-4	8	61	302	8	9	92
3	boyfriend (w	Ariana Grand	dance pop	190	80	40	-4	16	70	186	12	46	85
4	Beautiful Peo	Ed Sheeran	рор	93	65	64	-8	8	55	198	12	19	86

Possible Solution #1: A 2D array (i.e., matrix)

Weaknesses:

- What are the row and column names? Need separate lists for them clumsy.
- Lists are O(N). We'd need 2 dictionaries just for column names

data = [][] col_nonne -rindex index -r col_nonne

EDA: without Pandas

						top50.csv	,						
				BeatsPer				Live				Speechi	
	TrackName	ArtistName	Genre	Minute	Energy	Danceability	Loudness	ness	Valence	Length	Acousticness	ness	Popularity
1	Senorita	Shawn Mend	canadian pop	117	55	76	-6	8	75	191	4	3	79
2	China	Anuel AA	reggaeton flow	105	81	79	-4	8	61	302	8	9	92
3	boyfriend (w	Ariana Grand	dance pop	190	80	40	-4	16	70	186	12	46	85
4	Beautiful Peo	Ed Sheeran	рор	93	65	64	-8	8	55	198	12	19	86

Possible Solution #2: A list of dictionaries

list		
ltem 1	=	{"Track.Name": "Senorita", "Artist.Name": "Shawn Mendes", "Genre": "Canadian pop",}
Item 2] =	{"Track.Name": "China", "Artist.Name": "Anuel AA", "Genre": "reggaetón flow", }
Item 3	=	{"Track.Name": "Ariana Grande", "Artist.Name": "boyfriend", "Genre": "dance pop", }

EDA: list of dictionaries

Possible Solution #2: A list of dictionaries

```
f = open("../data/top50.csv", encoding = "ISO-8859-1")
column_names = f.readline().strip().split(",")[1:] # puts names in a list
cleaned column names = [name[1:-1] for name in column names]
cleaned column names.insert(0, "ID")
dataset = []
# iterates through each line of the .csv file
for line in f:
    attributes = line.strip().split(",")
    # constructs a new dictionary for each line
    dataset.append(dict(zip(cleaned_column_names, attributes)))
```

Possible Solution #2: A list of dictionaries

Q2: Write code to print all songs (Artist and Track name) that are longer than 4 minutes (240 seconds):

```
for song in dataset:
    if int(song["Length."]) > 240:
        print(song["Artist.Name"], "-", song["Track.Name"], "is", song["Length."], "seconds long")
```

Possible Solution #2: A list of dictionaries

Q3: Write code to print the most popular song (artist and track) – if ties, show all ties.

```
max_score = -1
most_populars = set()
for song in dataset:
    if int(song["Popularity"]) > max_score:
        most_populars = set([str(song["Artist.Name"] + "-" + song["Track.Name"])])
        max_score = int(song["Popularity"])
    elif int(song["Popularity"]) == max_score:
        most_populars.add(str(song["Artist.Name"] + "-" + song["Track.Name"]))
print(most_populars)
```

Possible Solution #2: A list of dictionaries

Q4: Write code to print the songs (and their attributes), if we <u>sorted</u> by their popularity (highest scoring ones first).

list		
ltem 1	=	{"Track.Name": "Senorita", "Artist.Name": "Shawn Mendes", "Genre": "Canadian pop",}
Item 2	=	{"Track.Name": "China", "Artist.Name": "Anuel AA", "Genre": "reggaetón flow", }
Item 3	=	{"Track.Name": "Ariana Grande", "Artist.Name": "boyfriend", "Genre": "dance pop", }

Cumbersome to move dictionaries around in a list. Problematic even if we don't move the dictionaries.

Possible Solution #2: A list of dictionaries

Q5: How could you check for null/empty entries? This is only 50 entries. Imagine if we had 500,000.

Possible Solution #2: A list of dictionaries

Q6: Imagine we had another table* below (i.e., .csv file). How could we combine its data with our already-existing *dataset*?

spo	otify_aux.cs	V	
	TrackName	ArtistName	ExplicitLanguage
1	Senorita	Shawn Mend	TRUE
2	China	Anuel AA	FALSE
3	boyfriend (w	Ariana Grano	TRUE
4	Beautiful Peo	Ed Sheeran	FALSE

* 3rd column is made-up by me. Random values. Pretend they're accurate.

EDA: with Pandas!

Kung Fu Panda is property of DreamWorks and Paramount Pictures and used here only for representation.

EDA: with Pandas

What / Why?

ŤUDelft

- Pandas is an *open-source* Python library (anyone can contribute)
- Allows for high-performance, easy-to-use data structures and data analysis
- Unlike NumPy library which provides multi-dimensional arrays, Pandas provides 2D table object called DataFrame (akin to a spreadsheet with column names and row labels).
- Used by *a lot* of people

EDA: with Pandas

How

- import **pandas** library (convenient to rename it)
- Use **read_csv()** function

import pandas as pd
dataframe = pd.read_csv("yourfile.csv")

EDA: with Pandas

Common Panda functions

High-level viewing:

- head() first N observations
- tail() last N observations
- columns() names of the columns
- describe() statistics of the quantitative data
- dtypes() the data types of the columns

EDA: with Pandas

Common Panda functions

Accessing/processing:

- df["column_name"]
- df.column_name
- .max(), .min(), .idxmax(), .idxmin()
- <dataframe> <conditional statement>
- .loc[] label-based accessing
- .iloc[] index-based accessing
- .sort_values()
- .isnull(), .notnull()

EDA: with Pandas

Common Panda functions

Grouping/Splitting/Aggregating:

- groupby(), .get_groups()
- .merge()
- .concat()
- .aggegate()
- .append()

Data Concerns

When determining if a dataset is sound to use, it can be useful to think about these four questions:

- Did it come from a trustworthy, authoritative source?
- Is the data a complete sample?
- Does the data seem correct?
- **(optional)** Is the data stored efficiently or does it have redundancies?

- Often, there may not exist a single dataset that contains all the information we are interested in.
- May need to merge existing datasets

• Important to do so in a **sound** and **efficient** format

Dataset 1

Top 200 most-frequent streams per day (for June 2019)

Dataset 2 Top 50 most streamed in 2019, so far

SpotifySongID, # of Streams, Date 2789179, 42003, 06-01 SpotifySongID, Artist, Track, [10 acoustic features] 200 2789179, Billie Eilish, bad guy, 3.2, 5.9, ... 3819390, 89103, 06-01 50 3901829, Outkast, Elevators, 9.3, 5,1, ... 4492014, 52923, 06-02 200 50 x 13 8593013, 189145, 06-02 6,000 x 3

We are interested in determining if songs with high danceability are more popular during the weekends of June than weekdays in June. What should our merged table look like? Concerns?

This is wasteful, as it has 10 acoustic features, artist, and track repeated many times for each unique song.

Datasets Merged (poorly)

6,000 x 15 → 90,000 cells

Some rows may have null values for # of Streams (if the song wasn't popular in June)

Datasets Merged (better)

SpotifySongID, Artist, Track, [10 acoustic features], 06-01 Streams, 06-02 Streams

50 x 43 → 2,150 cells

- Is the data correctly constructed (or are values wrong)?
- Is there redundant data in our merged table?
- Missing values?

The Parable of Google Flu: Traps in Big Data Analysis

David Lazer, 1,2* Ryan Kennedy, 1,3,4 Gary King, 3 Alessandro Vespignani 5,6,3

n February 2013, Google Flu Trends (GFT) made headlines but not for a reason that Google executives or the creators of the flu tracking system would have hoped. Nature reported that GFT was predicting more than double the proportion of doctor visits for influenza-like illness (ILI) than the Centers for Disease Control and Prevention (CDC), which bases its estimates on surveillance reports from laboratories across the United States (1, 2). This happened despite the fact that GFT was built to predict CDC reports. Given that GFT is often held up as an exemplary use of big data (3, 4), what lessons can we draw from this error?

The problems we identify are not limited to GFT. Research on whether search or social media can predict x has become common-

place (5-7) and is often put in sharp contrast with traditional methods and hypotheses. Although these studies have shown the value of these data, we are far from a place where they can supplant more traditional methods or theories (8). We explore two issues that contributed to GFT's mistakes big data hubris and algorithm dynamics and offer lessons for moving forward in the big data age.

COM

. . . .

ability and dependencies among data (12). The core challenge is that most big data that have received popular attention are not the output of instruments designed to produce valid and reliable data amenable for scientific analysis.

The initial version of GFT was a particularly problematic marriage of big and small data. Essentially, the methodology was to find the best matches among 50 million search terms to fit 1152 data points Large errors in flu prediction were largely avoidable, which offers lessons for the use of big data.

run ever since, with a few changes announced in October 2013 (10, 15).

Although not widely reported until 2013, the new GFT has been persistently overestimating flu prevalence for a much longer time. GFT also missed by a very large margin in the 2011-2012 flu season and has missed high for 100 out of 108 weeks starting with August 2011 (see the graph). These errors are not randomly distributed. For example, last week's errors predict this week's errors (temporal autocorrelation), and the direction and magnitude of error varies with the time of year (seasonality). These patterns mean that GFT overlooks considerable information that could be extracted by traditional statistical methods.

Even after GFT was updated

in 2009, the comparative value of the algorithm as a stand-alone flu monitor is questionable. A study in 2010 demonstrated that GFT accuracy was not much better than a fairly simple projection forward using already available (typically on a 2-week lag) CDC data (4). The comparison has become even worse since that time, with lagged models significantly outperforming GFT (see the graph). Even 3-week-old CDC data do a better job of projecting current flu prev-
